

Labor Market Policy as Immigration Control: The Case of Temporary Protected Status[‡]

July 12, 2018

Abstract: Controlling immigration has become a central political goal in most advanced democracies. Policymakers have attempted to leverage international economic flows – notably aid and trade – hoping that it will spur economic development in migrant origin countries and, by consequence, decrease subsequent demand for entry. We argue instead that policymakers in destination countries can manage the demand for migrant inflows by promoting policies that grant or enhance formal labor market access to those who have already emigrated from developing countries. Labor market access-enhancing policies increase remittances to migrant origin countries, raising consumption and reducing the propensity for other household members to migrate. We investigate one such labor market migration policy in the US: the provision of Temporary Protected Status (TPS) to immigrants residing in the United States. We find that TPS increases remittances to countries whose migrants are eligible and decreases both legal and illegal immigration to the US in the process.

I. Introduction

Controlling immigration, particularly from the developing world, has become a central political goal for most advanced democracies. Faced with migrant crises and increasingly influential anti-immigrant political movements, politicians across OECD destination countries have experimented with a range of policies to limit immigration from the Global South. While the building of border walls and fences may be the proposal *de jour*, for years, policymakers have attempted to leverage international economic flows – notably foreign aid and trade – hoping that it will spur economic development in migrant origin countries and, by consequence, decrease subsequent demand for entry (Asencio et al. 1990; Khoudour-Casteras 2009; Peters 2014). The European Union, for example, charges its development assistance agencies with addressing the “root causes” of immigration, while the United States in the 1990s considered

decreasing Mexican immigration a central goal of NAFTA (Knoll and Sherriff 2017; Johnson 1994). There is a growing skepticism, however, that increased aid and trade can actually reduce immigration, documented or undocumented, from the developing world (Clemens and Postel 2017). This skepticism is driven, in part, by concerns that trade and aid do not necessarily impact individuals at the lower end of the income distribution and, if they do, the increment to income provided by additional trade or aid actually facilitates migration by reducing financial constraints.

This does not mean that policies in destination countries are ineffective in decreasing the demand for immigrant entry. We argue that policymakers in destination countries can effectively manage the demand for migrant inflows by promoting policies that grant or enhance formal labor market access to those who have *already* emigrated from developing countries. Such policies give immigrants a better chance at obtaining employment that, on average, pays higher wages than if they did not have formal labor market access. We argue, harnessing models from the New Economics of Labor Migration (NELM), that countries whose immigrants economically benefit from these labor market access-enhancing policies will receive increased remittances as a result. Remittances, which unlike foreign aid or trade flows directly accrue to households, substantially increase incomes in migrant origin countries (Adams and Page 2005; Taylor 1999), raising consumption in the process and reducing the propensity for other household members to migrate for economic opportunity. In other words, policies that augment labor market opportunities for immigrants allow households in the developing world to more effectively diversify economic risk via increased remittances, serving as a substitute for subsequent immigration.

To test our argument, we investigate one such labor market migration policy in the US: the provision of Temporary Protected Status (TPS) to immigrants residing in the United States. Established by Congress in 1990, TPS grants temporary legal status to foreign nationals from nations experiencing excessively difficult living conditions but who do not legally qualify as refugees. These conditions may be borne from natural disaster, political and economic instability, or violent conflict. Managed by the Secretary of Homeland Security but in close consultation with the President, TPS offers two crucial benefits to foreign nationals that make it an ideal case to test our argument: a temporary shielding of deportation proceedings *even if* the migrant entered the US illegally or has overstayed their visa, and legal access to the formal labor market. TPS is initially granted for two years, can be renewed indefinitely, but can also be

terminated at the discretion of the executive branch. We expect countries whose migrants receive TPS to receive more remittances than countries whose migrants are not TPS-eligible. And we show, both theoretically and empirically, that this increase in remittances *decreases* the demand for entry – both legal and illegal – into the United States.

By examining the effect of executive actions on immigration, this paper makes a number of contributions to the broader international relations literature. First, we add to a small but growing literature examining how advanced democracies control international migration. Our theoretical argument and findings suggest an alternative to popular, but empirically unverified, policies related to aid and trade: granting labor market access to those who have already migrated decreases subsequent migration. Second, we contribute to the literature on the wide-reaching effect of remittances, one of the world’s largest and most underexplored financial flows.¹ Finally, we engage with competing theoretical models of international migration, offering an empirical test of an approach called the New Economics of Labor Migration (NELM) that has emerged as an alternative to the more standard, neoclassical understanding of migration (Massey, et al 1993).

Our arguments and evidence are presented as follows. In Section Two, we develop the argument linking labor market access-enhancing policies for immigrants to models of bilateral migration flows. That section provides a contextual discussion of the particular policy of interest — that of TPS. In sections Three, Four, and Five, we empirically evaluate the effect of TPS on three outcome variables: remittances, legal immigration to the US, and illegal immigration to the US. In Section Six, we use the method of synthetic control to address the question: what would remittances and immigration from countries such as El Salvador and Honduras be had their expatriates not received TPS? Section Seven concludes.

II. Reducing Immigration and TPS: Theory and Hypotheses

There is an emerging literature on how foreign and domestic policy in advanced democracies affects migrant inflows, especially from developing countries. This literature has grown as politicians increasingly hold a mandate to curb immigration, while their countries continue to be sought-after destinations for migrants from across the globe. In the wake of

¹ See Singer (2010) for an overview of the importance of remittances.

migration crises in Europe and the US over the past few decades, politicians in industrialized states have argued that channeling international economic flows like foreign aid and international trade to migrant origin countries can significantly decrease South-North migration.² Scholars and policymakers have argued that these flows can address the root causes of immigration, such as poverty, conflict, and widespread youth unemployment (EU Trust Fund for Africa 2016). If aid and trade can ameliorate these conditions in origin countries, so the argument goes, then they can ultimately reduce immigration. Indeed, there is substantial evidence that donor countries target foreign aid at countries from which they receive large numbers of migrants, at least partially in hopes of decreasing the demand for entry from those countries (Bermeo and Leblang 2015; Vazquez and Sobrao 2016; Czaika and Mayer 2011). There is also evidence that advanced democracies view international trade policies through an immigration lens. Perhaps the most prominent example is the US perspective on regional trade agreements like NAFTA and CAFTA as market-oriented policies to reduce the demand for entry from Mexico and Central America, respectively.³

Despite the growing popularity of treating foreign aid and trade as immigration policy, there remains a significant lack of empirical evidence that they actually affect migratory flows. This point is perhaps best noted by Clemens and Postel (2017), who argue that skepticism is warranted when it comes to crediting foreign aid in particular as an immigration panacea for three major reasons. First, they contend that the jury is still out on if donors meaningfully consider the causes of immigration in their aid allocations. Second, even if donors channel aid

² Examples of governments touting foreign aid and trade policy as solutions to immigration abound. Former Austrian Foreign Minister Sebastian Kurz stated in front of the United Nations that “to address the root causes of migration, we decided to double our direct bilateral development cooperation” (Statement by H.E. Sebastian Kurz). President Clinton in his remarks at the NAFTA signing ceremony claimed that “there will be less illegal immigration because more Mexicans will be able to support their children by staying home” (Remarks by President William J. Clinton).

³ In addition to the President Clinton quote cited above, President George W. Bush stated that “If you're concerned about immigration to this country, then you must understand that CAFTA and the benefits of CAFTA will help create new opportunity in Central American countries, which will mean someone will be able to find good work at home, somebody will be able to provide for their family at home, as opposed to having to make the long trip to the United States. CAFTA is good immigration policy, as well as good trade policy” (quoted in Gelatt and Davy 2005).

along immigration routes, foreign aid is likely to be insufficient in magnitude to address the causes of immigration (Qian 2015; Clemens et al. 2012). Finally, it is unclear that increasing incomes and decreasing unemployment in origin countries would actually curb immigration, even if aid could accomplish this. Substantial evidence suggests that sustained economic growth can actually *encourage* emigration from initially low-income countries (de Haas 2007; Clemens 2014; Dao et al. 2016). The claim that fostering free trade between origin and destination states can reduce immigration is similarly belied by the empirical record surrounding NAFTA and CAFTA, as immigration from Central America and Mexico to the US has persisted, despite the fact that these regional trade agreements were touted as containing policies to reduce immigration.

If foreign aid and trade policy are ineffective at decreasing immigration, are there other policy tools to which countries can turn? We focus on a different class of policies that, while not used intentionally to manage migrant inflows, have the potential to accomplish this crucial political goal. Governments have the power to restrict, or enhance, economic opportunity for migrants by regulating their ability to enter the formal labor market. We argue that when advanced democracies enhance immigrant access to the formal labor market, they can also reduce subsequent immigration from developing countries. In this sense, providing additional economic opportunity to those who have *already* migrated can have large effects on the demand for entry from the developing world.

Labor market access-enhancing policies are an economic boon for eligible immigrants. For instance, Rivera-Batiz (1999) and Kossoudjii and Cobb-Clark (2002) find that obtaining a green card—a shift to permanent legal status in the United States—increases the wages of an immigrant by 6 to 13 percent on average.⁴ Devillanova et al. (2017) find, in the Italian context, that when undocumented immigrants are eligible for amnesty, they are significantly more likely to find employment than those who are ineligible. Kaushal (2006) finds a similar result in the US. In the case of TPS, a policy we discuss in detail below, the economic benefits to immigrants are similarly large. Orrenius and Zavodny (2015) find that Salvadoran immigrants with TPS are

⁴ Amuedo-Dorantes and Bansak (2011) and Pan (2012) reach differing conclusions with regard to the effect of legal permanent resident status on employment for women, with Amuedo-Dorantes and Bansak (2011) finding that women are more likely to exit the workforce once they obtain status while Pan (2012) finds the opposite effect for women.

more likely to find employment as compared to Salvadorans in the US illegally and that, on average, the jobs they find pay higher wages.

These increased incomes of migrants can also increase remittances, or income sent from migrants to family members back home. Direct evidence on this point is limited, as data enabling scholars to establish a causal link between labor market access and remittances does not exist. However, in a set of papers, Bollard, McKenzie, and Morton (2009) and Bollard, McKenzie, Morton and Rapoport (2011) exploit surveys of migrants residing in the US, France, Germany, Italy, Spain, and Australia. Using this micro-level data, they find that even after controlling for a migrant's gender and their level of education — along with a battery of other demographic, economic, and social characteristics — higher wages are associated with an increase in both the frequency and amount of remittances that migrants send home. While we do not have access to micro-level data that allows us to ascertain whether migrants granted TPS remit more, in the aggregate, we hypothesize that when immigrants gain access to the formal labor market as a result of such policies, their homelands will receive larger flows of remittances.

But how can these policies, and the associated increase in remittances, influence subsequent inflows of migrants from affected countries? We know that that remittances serve to increase and smooth household consumption patterns in the Global South. For instance, Adams and Page (2005) find that remittances significantly reduce poverty in developing countries. Combes and Ebeke (2011) meanwhile find that remittances decrease household consumption instability and also act as insurance in the face of natural disaster or economic crisis. Remittances also allow households in developing countries to accumulate savings and overcome local credit market deficiencies (Stark 1984). In other words, increased remittances can act as a *substitute* for subsequent immigration of household members, as remittances augment household income in the migrant's homeland. Therefore, we hypothesize that the increase in remittances associated with labor market access-enhancing policies for immigrants should *decrease* subsequent immigration from affected countries.

Note that this hypothesis is at odds with neoclassical models of migration which see aid and trade as decreasing the financial constraint and, in turn, *increasing* the likelihood of migration. Remittances are different from aid and trade flows for at least two reasons. First, remittances accrue directly to households in developing countries (Escriba-Folch et al. 2015), meaning that they directly affect patterns of immediate consumption among recipient

households. This is in stark contrast to aid or trade flows which, if they do have an effect on the household, that effect takes (much) longer to observe (Qian 2015; McKenzie 2017; Rodriguez and Rodrik 2000; Yanikkaya 2003). Second, remittances are orders of magnitude larger than most other international economic flows, especially foreign economic assistance. In recent years, remittances to developing countries are more than three times larger than foreign aid, and this gap has only grown over time. Remittances are also comparable in size to private debt and portfolio equity flows, and only lag foreign direct investment among all global financial flows (World Bank 2016). While scholars remain skeptical that paltry aid flows can have a significant impact on the causes of emigration from the developing world, remittances may be able to pack a more powerful punch.

Our characterization of remittances' effect on the household draws on the New Economics of Labor Migration (NELM) literature. This literature emerged in response to the more traditional neoclassical understanding of international migration. NELM models argue that migration decisions – especially from countries in the Global South – are made by the family/household unit and not the individual (e.g., Stark and Levhari 1982; Stark 1984; Katz and Stark 1986; Massey et al. 1993). The rationale underlying the NELM is one that gives pride of place to economic risk: because labor markets in developing countries are often volatile, insurance markets are underdeveloped, and programs of government support are limited or nonexistent, migration is part of a household's strategy to diversify its labor portfolio, which helps decrease potential risks to its long-term income (Massey 2009).

Remittances play a crucial role in a household's risk diversification strategy and are therefore given pride of place in the NELM. As we discuss above, remittances help the migrant's family smooth consumption in the face of domestic (home country) volatility and reduce local credit constraints that the migrant's family faces (Stark 1984). Whether invested or used for consumption, the NELM views remittances as a mechanism that bolsters economic development in migrant sending countries (Taylor 1999).⁵ While neoclassical models—which privilege wage maximization — may fit patterns of migration between industrialized countries, scholars of migration from the Global South argue that these decisions are made by households, rather than by individuals (e.g., Massey 2009).

⁵ This effect is not without controversy. In a recent paper, Clemens and McKenzie (2014) discuss problems in identifying the overall effect of remittances on home country economic growth.

In summary, we expect policies that open the formal labor market to immigrants will a) increase the incomes of immigrants who already reside in an industrialized state, b) increase the amount of remittances sent home to friends and family by immigrants who benefit from these policies, and c) reduce subsequent immigration to that industrialized state, both documented and undocumented. We focus on remittances as an international financial flow that is distinct from other flows like foreign aid or international trade, and we suggest policies that increase remittances can affect subsequent immigration in unexpected ways.

TPS: A Brief Overview

To test our argument, we take TPS in the US as a particular case of labor market-enhancing policy for immigrants already present in the country. TPS is the product of a long and rich history of executive actions on immigration to the United States. Every president in the post-World War II era has deployed blanket protections for immigrant groups from certain countries facing hardship.⁶ With Congress unwilling to act, President Truman issued executive grants of relief following World War II for groups targeted and displaced by Nazi Germany. Kennedy extended and expanded protections to Cubans due to the Cuban Revolution. Carter suspended deportation proceedings for 250,000 Silva letter-holders in 1977,⁷ while Reagan provided a similar protection for 200,000 Nicaraguan refugees in 1987. President H.W. Bush continued this tradition of shielding individuals from deportation by extending Reagan’s “family fairness” policy to 100,000 spouses in 1990, and Bill Clinton similarly halted deportation proceedings for 40,000 Haitians in 1997 over concerns about political instability in that island nation.

Over the course of the 1980s, both members of Congress and the public at large grew concerned about what they viewed as an arbitrary — and increasingly political — use of executive actions to protect migrant populations. Most noticeably, concerns over the Reagan Administration’s refusal to grant El Salvadorans either refugee status or other blanket protections

⁶ See Appendix A for a near-exhaustive list of executive actions on immigration since WWII.

⁷ In 1977, due to a lawsuit involving Cuban visas and immigration quotas for the Western Hemisphere, a federal court ordered the Immigration and Naturalization service to issue documents to Mexicans present in the US that shielded them from deportation and allowed them to gain employment. These documents came to be known as Silva letters due to the namesake of the court case, and Silva letter holders were either allowed to apply for visas or were granted legal permanent residency with the 1986 Immigration Reform and Control Act (IRCA).

led to congressional action, which culminated in the Immigration Act of 1990 (Anchors 2007). The Immigration Act of 1990 created TPS, the focus of the empirical section of this paper. TPS was designed to eliminate politicized executive actions on immigration policy, instead placing the focus on conditions on the ground in crisis-affected countries. TPS can be granted – and terminated – at the discretion of the executive branch.

As noted above, TPS provides blanket relief for citizens of a crisis-affected country who were present in the US when a crisis hit their home country. Those who receive protected status are able to legally enter the labor market—whether the migrant is present in the US legally or illegally.⁸ For those who entered the US on temporary work visas, TPS crucially provides a blanket extension of that status. More generally, TPS can operate quasi-permanent legal status: some immigrants, such as those from El Salvador and Honduras, have held TPS for more than two decades. Because of these central provisions, executive actions related to granting TPS fit squarely into the class of labor market-enhancing policies for immigrants who are already present in the US. We hypothesize that when a country’s migrants residing in the US are eligible for TPS, those countries will receive increased income in the form of remittances as compared to countries whose migrants are TPS-ineligible.⁹ We also hypothesize that these remittances will reduce subsequent immigration into the United States, both documented and undocumented.

III. TPS and Remittances

We examine the empirical effect of TPS on remittances by constructing a panel of countries observed from 1990 through 2015. Our ‘global’ sample is comprised of all non-OECD countries (excluding Chile, Israel, Mexico, and South Korea) for which data are available that

⁸ TPS allows for legal labor market access regardless of whether the migrant entered the US illegally or legally and overstayed their visa. TPS allows both legal and illegal migrants to remain in the country and not fear deportation, so long as the individual does not commit a criminal offense (a felony).

⁹ It is important to recall, however, that the NELM framework is based on the idea that families insure against risk through migration. A large literature indeed finds that even without any policy change in the migrant’s host country, exogenous shocks such as a natural disaster or civil war in a migrant’s homeland result in increased remittances to that country (e.g., Yang 2011, Naude and Bezuidenhout 2014). Despite remittances being counter-cyclical, we expect TPS, because it provides all legal and illegal migrants access to the labor market, to be associated with an even larger increase in remittances.

are not in the World Bank’s high-income category. The inclusion of a number of covariates — especially the use of a variable measuring the number of migrants from a country residing in the US — restricts our sample to 138 countries. Within the usable sample of countries, TPS was granted to migrants from twelve countries: Bosnia and Herzegovina, Burundi, El Salvador, Guinea, Honduras, Haiti, Liberia, Nicaragua, Nepal, Rwanda, Sierra Leone, and Yemen.¹⁰ A list of countries in the sample are included in Appendix B; specifics with regard to measurement and data sources are included in Appendix C.

As all of our data are observed on an annual basis, we code TPS as “1” for the year that a country was designated with this status. A country continues to be coded as having TPS until that status officially ends; that means that renewals of TPS continue to be coded as “1.” In all other cases, TPS is coded as zero. Protected status was coded based on TPS notices held by the US Department of Justice.¹¹

The dependent variable, “Remittances/GDP”, measures remittances received by country i at time t as a share of that country’s gross domestic product. In alternate specifications, we also use “Remittances/Pop”, which measures remittances on a per-capita basis.¹² Macroeconomic models of remittances emphasize both conditions in home and host countries.¹³ These include the size of the country’s expatriate population, as a larger expatriate population should be a source of more remittances, all else equal. Given that we are looking at TPS as applied to migrants who reside in the US, we measure the expatriate population as the log of the number of foreign born from country i residing in the US at time t .

¹⁰ We were unable to include five TPS countries – Angola, Kosovo, Somalia, South Sudan, and Syria – in our sample due to lack of data on remittances.

¹¹ See <https://www.justice.gov/eoir/temporary-protected-status> for these notices.

¹² It is important to note that our measure captures remittances from all countries in the world, not just the United States. On average, the United States is the source of approximately 60% of all remittances; for countries in the Western Hemisphere the United States is the source of 98% of all remittances (author’s calculations based on the World Bank’s bilateral remittance matrix for 2010 <http://www.worldbank.org/en/topic/migrationremittancesdiasporaissues/brief/migration-remittances-data>).

¹³ See the review in Leblang (2017).

Other determinants of remittances include exchange rate depreciation — as a currency depreciates vis-à-vis the US dollar, we expect an increase in remittances from the US, as these remittances will net more consumption or investment in real terms. To capture the potential influence of exogenous shocks to a country, we include two variables: a dummy variable coded “1” during periods of civil war and another that measures the number of natural disasters experienced by the country at time t . Because TPS provides a migrant with access to the labor market, we include two variables to proxy for the health of the US economy: the log of the annual average weekly wage in the United States and the US’s annual unemployment rate. We expect, all else equal, that higher average wages will translate into higher remittances, while a higher unemployment rate will have the opposite effect. Finally, we control for the size of a country’s population and its GDP per capita, both in log form.

Table 1 displays our initial findings. All models are estimated using ordinary least squares and include a set of country dummy variables to account for unmeasured country-specific factors that may be associated with remittances. Robust standard errors clustered by country are in parentheses. All variables are lagged by one year to decrease the chance of simultaneity.

Columns 1-3 in Table 1 correspond to different estimation samples: column (1) includes all countries that are not in the World Bank’s high-income category, column (2) excludes both high-income and upper middle-income countries, and column (3) restricts the sample to countries in the Western Hemisphere (excluding Canada). In all three samples, TPS has a positive and statistically significant effect of remittances. When TPS is in force, remittances as a share of GDP experience a massive increase—almost tripling from the average of 2.7% of GDP to close to 9% of GDP in column (1), from 3.2% of GDP to 8.2% of GDP in column (2), and from 2.4% of GDP to 7.2% of GDP in column 3. When we estimate the model using per capita remittances¹⁴, we find similarly large effects: when TPS is in force we estimate an increase of per-capita remittances of almost one hundred dollars (measured in 2010 US dollars) per person—from an average of one hundred fifty dollars to almost two hundred and fifty dollars.¹⁵

¹⁴ These results are not reported here to save space but are available in Appendix Table D-1.

¹⁵ We also estimate the same model for all three samples with foreign aid receipts from the US as a percentage of GDP as the dependent variable; these results are available in Appendix Table D-2. We find that TPS has no statistically significant effect on foreign aid receipts from the US.

The effect of the included control variables is mixed: consistent with existing literature, we find a positive and statistically significant effect of the migrant population from country i residing in the US (larger migrant populations increase remittances). The other variables show different patterns depending on the sample: increases in US wages or unemployment have the expected effect — wages increase while unemployment decrease remittances depending on the sample. Most interesting are the variables measuring exogenous shocks—natural disasters or civil conflicts. In no specification are natural disasters, exchange rate depreciation, or civil war statistically significant predictors of remittances. This latter result may be consistent with a growing body of literature suggesting that remittances, by smoothing consumption, may decrease the likelihood of the onset of a civil war (Regan and Frank 2014).

As a robustness check, we re-estimate the model in Appendix Table D-3 using the Arellano-Bond dynamic panel data estimator. This estimator allows efficient estimation of a lagged endogenous variable — to account for the possibility that remittances may be a trending variable — in the presence of country fixed effects. These results are consistent with those in Table 1, though the effect of TPS is understandably attenuated.

These results show that, at least in the aggregate, countries whose migrants receive TPS protection receive larger flows of remittances. Our estimates suggest that this effect can be quite large, whether measuring remittances as a proportion of GDP or on a per capita basis. Does this increase in remittances influence the flow of migrants to the United States? In the next two sections we investigate the effect of TPS and remittances on legal and illegal migration to the United States.

IV. TPS and Legal Immigration to the United States

We hypothesize that TPS will influence the demand for migration into the US through the effect of protected status on remittances. The effect of remittances on migration is ambiguous: from the perspective of the financial constraint literature, all else equal, an additional dollar of income should increase a potential migrant's liquidity, allowing them to migrate. The NELM approach, however, suggests that because migration is a strategy to diversify family income,

remittances should actually weaken the draw of foreign labor markets.¹⁶ In this section we utilize novel data on migration to the United States to distinguish between these two predictions.

Existing studies of migration tend to draw on census data to measure the inflow of migrants into a destination country. Those data, however, fail to distinguish between migrants who have recently entered the country and those who have adjusted their visa status. We draw on data from the Department of Homeland Security (post-2000) and from the Immigration and Naturalization Service (pre-2000) to measure *legal* immigration as a count of the number of new arrivals into the US in year t from country i .¹⁷ As our interest is in the effect of TPS on migration—through its effect on remittances — into the US, we limit our attention to immigration from countries in the Western Hemisphere (excluding Canada). Narrowing our focus in this way is substantively reasonable, as the majority – over two-thirds — of new arrivals to the US each year come from the Western Hemisphere.

Individual-level models of immigration emphasize utility maximization and argue that migration occurs when the expected wage at a potential destination (in this case the US) is greater than the expected wage in the migrant’s homeland less the costs of migrating. This micro-level framework has been modified to include a variety of macro-level determinants and to broaden the conceptualization of migration costs.¹⁸ We include a wide battery of variables to capture the push and pull factors driving migration to the United States. From the perspective of both the NELM and standard micro-economic models, migration is driven by economic factors such as relative wages (home country GDP/US GDP), relative economic inequality (home

¹⁶ Because we are interested in the effect of TPS, our focus is on immigration to the US. However, we recognize that the inflow of remittances could decrease emigration to other nations as well.

¹⁷ An advantage of using data from DHS and INS is that they separate immigration into new arrivals and adjustments of status. The former category — which we use — measures the number of people applying for and receiving a green card through a US consular service. Adjustments of status, on the other hand, capture individuals already present in the US who have adjusted their visa status to a green card.

¹⁸ See Stark (1984); Clark, Hatton, and Williamson (2007); Hatton and Williamson (2002); and Fitzgerald, Leblang, and Teets (2014), which contain reviews and empirical tests of these models.

country GINI Index/US GINI index), and relative education (home country educational attainment/US educational attainment).

As migration is inherently risky, scholars stress the importance of social networks — friends and family — in helping decrease the social and informational costs associated with cross-border migration. We measure social networks as the log of the size of the foreign-born population from a country of origin residing in the US.¹⁹ We also include two variables to capture factors that potentially “push” migrants to exit their country: the annual number of natural disasters in the country of origin (in log form) and the existence of an ongoing civil war. Finally, we control for foreign aid receipts from the US as a percentage of GDP to ensure that aid is not driving the relationship we observe between TPS, remittances, and new arrivals to the US. As the dependent variable is the number of new arrivals, we include the log of the size of population in the country of origin to control for the pool of potential migrants.

We estimate the effect of remittances and TPS on new arrivals — our measure of legal migration — from 24 countries in the Western Hemisphere over the years 1989-2015²⁰ using a Poisson model.²¹ We prefer a Poisson model to OLS because the dependent variable (a) is bounded on the left by zero and (b) the dependent variable is a discrete count of legal migrants into the US. The inclusion of fixed effects for countries of origin accounts for omitted variables that remain constant within country and obviates the need for variables suggested by gravity models of international migration.²²

¹⁹ It is important to note that the stock of the foreign-born population can also have a policy interpretation within the context of legal migration to the US. As the vast majority of immigrant visas are issued for the purpose of family reunification, the foreign-born population can be interpreted as a proxy for the number of families who are attempting to reunify with family members from abroad.

²⁰ Missing data for some of the covariates – including remittances – reduces the size of the sample in some years. Countries included in the sample are listed in Appendix B.

²¹ Santos Silva and Tenreyro (2006) demonstrate that the Poisson model is preferable to both OLS and negative binomial specifications when the model contains high dimensional fixed effects; they show that under these conditions, the Poisson model produces unbiased parameter estimates.

²² Gravity models of international migration — like gravity models of international trade — hold that dyadic flows of people (or goods) are influenced by transactions costs. These costs are generally measured by the inclusion of variables such as bilateral distance, whether the countries

Column (1) of Table 2 contains the results of the fixed effects Poisson model. Surprisingly, most of the control variables — other than the source country’s population and the size of the foreign-born population — are statistically indistinguishable from zero.²³ As anticipated, and consistent with earlier findings, migration from country i to the US increases with the existing size of the foreign-born population from that country and decreases as the wage gap decreases. All else equal, countries in the Western Hemisphere with larger populations are sources of a larger number of migrants to the United States.

Our variable of interest is remittances as a share of the migrant’s country of origin GDP. From the perspective of the NELM, an increase in remittances should decrease the demand for migration. But as we noted earlier, literatures related to the mobility transition and the importance of liquidity constraints expects that each additional dollar remitted should increase the ability of individuals to migrate. The estimated coefficient on remittances as a share of GDP in column (1) of Table 2 is negative and statistically significant.²⁴

To get a sense of the magnitude of the effect of remittances on legal migration, note that the average number of new arrivals from countries in the Western Hemisphere is 5,730, with a standard deviation that is over twice the mean (11,878). Meanwhile, average remittances as a share of origin country GDP is approximately 4.5 percent, with a standard deviation of about 5. Holding all else constant, increasing remittances by one standard deviation *decreases* new arrivals into the US by twenty-three percent (from 6,700 to approximately 5,100) per annum. Figure 1 illustrates the marginal effects of the log of remittances as a percentage of GDP on the predicted number of new arrivals to the US. As expected, holding all other variables at their

share a common official language, a common border, and/or a common colonial heritage. As these variables do not vary over time, the inclusion of origin country fixed effects eliminates the need to explicitly include these gravity controls.

²³ Interestingly, this is not due to the inclusion of country fixed effects. Removing the fixed effects renders the education ratio statistically significant, but the remainder of the control variables remain insignificant.

²⁴ We explored the potential for nonlinearity in the effect of remittances on migration into the US by entering remittances/GDP along with its square. In those results, not reported here, both parameters are negatively signed but neither is individually significant due to a high level of collinearity (correlation is .94).

means, an increase in remittances as a percentage of GDP yields a statistically significant and substantively important decrease in arrivals of new migrants to the United States.

One may be skeptical with regard to the estimated size of this coefficient: it is known that measures of remittances are often (massively) underestimated.²⁵ As a robustness check, in column (2) of Table 2, we replace the remittances variable with the TPS dummy variable. That variable is statistically significant and is also negative: all else equal, immigration from countries whose migrants are TPS-eligible decreases by approximately twenty-four percent (from 5,635 to 4,251). In column (3) we include both variables and, surprisingly, both are statistically significant and negative. One plausible explanation for this is that, as noted earlier, remittances are under-reported; because TPS provides access to the labor market, it provides migrants with the opportunity to obtain higher wages which, in turn, yields higher remittances—either through official or unofficial channels. These remittances, in turn, decrease the need for additional family members to seek labor market opportunities in the US.

V. TPS and Illegal Immigration to the United States

The NELM logic linking remittances to a decrease in the demand for legal immigration should hold for illegal immigration as well. As discussed above, families use migration as a mechanism to diversify sources of income. If legal immigration is not a possibility, all else equal, the NELM logic would hold for illegal methods of entry into a foreign labor market. Existing scholarship shows that illegal immigrants from Mexico, on average, earn higher wages in the US than they would at home, even though their wages are lower than what would be obtained in the legal labor market (Hanson and Spilimbergo 1999). And, given that the logic of the NELM is not about relative wages per se, but about the diversification of income streams, the key consideration is accounting for the risk that a family member will be caught when attempting to enter a country (labor market) illegally. We turn to the measurement of risk below.

The challenge in applying our argument to illegal immigration is measurement. Assuming that immigration authorities want to prevent illegal entry,²⁶ observing illegal

²⁵ See Mohapatra and Ratha (2011) and World Bank (2006) and Clemens and McKenzie (2014) for an opposing view.

²⁶ A crack-down on illegal migrants would hinder the labor supply and push up wages in sectors such as agriculture, construction, and hospitality. That would decrease wages for business

immigration is difficult if not impossible. While there are a number of approaches to estimating illegal immigration (e.g., Hofer, Rytina, and Baker 2007; Passel and Cohn 2016), these estimates are problematic for two reasons. First, these approaches use data from the US Decennial Census and/or the American Community Survey to generate estimates of the *stock* of the foreign-born population that is in the US illegally. As such, they are unsuitable for measuring the annual *flow* of illegal migrants into the country. Second, the measures of the stock of illegal migrants cannot distinguish those who have entered the US illegally from those who entered legally and overstayed their visas. Consequently, even taking first differences of the stock measures would not generate accurate estimates of the inflow of illegal migrants.

As we cannot directly observe the number of illegal entrants into the US, our approach is to proxy for the demand for illegal entry by using data on the number of people attempting to enter the US without inspection at air and sea ports of entry and at the southern border of the US. We obtain data on the number of individuals apprehended by Customs and Border Patrol (CBP) each year, broken down by country of origin, and use this as our measure of the demand for illegal entry into the US. While imperfect, assuming “that the *apprehension rate* is constant, changes in apprehensions are a direct indicator of changes in illegal inflows” (Office of Immigration Statistics 2017).

We cannot know if the apprehension rate is constant, but we can model the factors that may influence apprehensions and include those factors in our empirical model. The first set of factors that influence apprehensions is related to border enforcement efforts at the Southern Border of the US and at other ports of entry. Some scholars use a variable for the number of CBP officers placed along the southern border (Bohn and Pugatch 2015).²⁷ Others use current line-watch hours as a proxy for enforcement, finding a negative relationship between line-watch hours and the number of apprehensions (Hanson and Spillimbergo 1999; Hanson 2006).

owners in some politically sensitive and geographically concentrated areas. See, for example, Root (2016) for a discussion of the sensitivity of illegal migration enforcement in Texas.

²⁷ These studies anticipate that, when controlling for the US unemployment rate, relative hourly wages in Mexico and the US, relative GDP per capita, output levels across commonly undocumented supplied labor industries, and a legislation indicator of 1 for implementation of the IRCA, an addition of 1,000 border patrol officers to a CBP sector outpost decreases the sector’s share of Mexican immigrants by 21.9% (Bohn and Pugatch 2015).

Unfortunately, the Department of Homeland Security stopped reporting and publishing information on line-watch hours after 2009, arguing that provision of these numbers supplied information to potential coyotes and smugglers. However, the total number of border patrol officers employed — a variable that we have continuous data for starting in 1980 — has a correlation of .987 with line watch hours.²⁸ Yet all models face challenges associated with endogeneity, as most models begin with a core assumption that the number of apprehensions in a given time period is a function of the number of illegal attempts to cross the border and a given level of border enforcement (Hanson and Spilimbergo 1999). To decrease the possibility that changes in the number of border patrol agents is caused by the number of apprehensions, we lag this variable by one year.

Existing studies of illegal migration also identify labor shocks in American economic sectors that typically rely on sources of undocumented labor as determinants of apprehensions. As demand for labor increases, all else equal, we should see an increase in demand for illegal entry (Bohn and Pugatch 2015; Hanson and Spilimbergo 1999). We proxy for labor demand using two variables: the seasonally adjusted unemployment rate in the US and the log of US housing starts, as construction employs an estimated 15 percent of all unauthorized migrant workers (Passel and Cohn 2016). Illegal immigration into the US may also be a result of a lack of visas for legal entry: assuming a constant visa cap, any increase in the demand for entry into the US may result in a diversion from legal to illegal migration. Consequently, we include a measure of the total number of visas (all categories) issued by the US in the prior year. Finally, some who enter the US without inspection do so in order to apply for asylum. Backlogs in

²⁸ However useful line-watch hours are as a predictive variable, Massey, et al. (2016) argue that line watch hours and total officer hours cannot adequately account for dramatic shifts in technology and standard operating procedures within CBP and INS. This argument is reasonable, as the Department of Homeland Security remains the most rapidly changing federal department and the CBP the most changed agency since the early 1990s (Espenshade 1995). When modeling apprehensions over time, changes in CBP protocol, initiatives, and technology must be more directly controlled for when attempting to measure border enforcement. Increasingly sophisticated border enforcement technologies, however, may not have a dramatic effect on apprehension rates because changes in technology do not necessarily deter migration; rather, they will increase the costs associated with moving by making hired guides and more remote crossing locations more attractive to potential migrants. Expenses are perceived both literally (via expensive coyote crossing) and in the form of forgone wages due to longer crossing trips (Gathmann 2008).

asylum courts may signal to potential migrants either that they will not be granted a hearing in timely fashion, or that immigration officials are purposively delaying hearing with the intent of deterring those who would seek asylum. We include a variable measuring the average number of days it takes for an asylum case to be heard, broken down by country of origin.

In addition to these variables focusing on the demand for illegal entry, we include the same base set of covariates that we used in the model of legal migration. We again control for foreign aid receipts from the US as a percentage of GDP to ensure that aid is not driving the relationship we observe between TPS, remittances, and apprehensions. In addition, we include the lagged level of apprehensions; this variable can account for unmeasured and persistent push factors that may generate a demand for illegal entry into the US, while at the same time proxying for the demand for increased border patrol or other enforcement efforts at the US border.

As with our models of legal migration, in Table 3 we estimate a series of Poisson models and include country of origin fixed effects. The effect of remittances on apprehensions — our proxy for the demand for illegal entry into the US — is negative and statistically significant in column (1). For this sample of countries, remittances as a share of GDP has a mean of six percent with a standard deviation of 6.75 percent. All else equal, increasing remittances by one standard deviation decreases the estimated number of apprehensions from about 7,100 to about 6,000 — a difference of slightly more than 1,100. Figure 2, analogous to Figure 1, illustrates the marginal effects of remittances as a percentage of GDP on the predicted number of apprehensions from a country in a given year. As expected again, holding all other variables at their means, an increase in the log of remittances as a percentage of GDP results in a significant decrease in annual apprehensions at the border.

The control variables in column (1) of Table 3 are a mixed bag. The lagged measure of apprehensions is, surprisingly, statistically insignificant, indicating that apprehensions at time $t-1$ do not predict apprehensions at time t . Both the ratio of home country GDP per capita and the ratio home country income inequality are correctly signed and statistically significant: the demand for illegal entry into the US increases with relative inequality and decreases as the wage gap declines. As with legal migration, both the size of the home country population and the education ratio are statistically insignificant.

The push factors—civil war and natural disasters—are both statistically significant, but not across all models. Civil wars, all else equal, increase the demand for illegal entry into the US,

as individuals flee violence and the potential loss of life associated with civil conflicts. It may be that civil war generates an increase in apprehensions as those individuals enter the US without inspection to seek asylum. Natural disasters, on the other hand, have a negative and statistically significant effect on apprehensions in Model (1). This effect is consistent with other recent scholarship, which finds that while natural disasters generate displacement of populations, those populations tend to remain within national borders, as disasters make it more difficult and expensive to move abroad (Beine and Parsons 2015).

The demand for illegal entry into the US also decreases with longer average wait times for asylum hearings; whether this is a variable that policymakers can manipulate for the purposes of deterring illegal entry is both a legal and normative question for a different paper. Consistent with other work, we find that increased staffing of the US CBP increases apprehensions. We also find that a strengthening US housing market—as measured by the (logged) number of housing starts — is also associated with an increased demand for illegal entry, as potential migrants see employment in the construction sector as an opportune way to diversify their family’s income streams. The coefficient on US unemployment is statistically insignificant. Finally, the lagged US visa cap is negative and significant, suggesting that individuals who cannot legally enter the US will, all else equal, attempt to enter illegally.

In column (2), we substitute the TPS dummy variable for the measure of remittances. In column (3), we include both variables simultaneously. As with the legal migration models, both remittances and TPS are negatively signed and statistically significant regardless of specification, with parameter estimates that are relatively stable. That both variables are statistically significant again suggests that even the best available estimates of official remittances underestimate the magnitude of financial flows sent home by migrants.

VI. Policy Analysis: Synthetic Control

Finally, we turn to evaluating TPS as a potential policy lever that executives can pull to decrease flows of immigrants from particular countries in the event of crisis. To do this, we zoom in on a collection of prominent TPS-eligible countries that we take as major case studies: El Salvador, Honduras, and Nicaragua. Our goal is to answer the counterfactual question: what would remittances inflows and immigration to the US from these countries look like had their migrants not received TPS following natural disasters?

We use synthetic control methods for comparative case studies as proposed by Abadie et al. (2010) to answer this question. The synthetic control method uses a transparent quantitative algorithm to generate a combination of control units that, conditional on identifying all relevant pre-treatment covariates, gives us the best comparison possible between a unit of interest that received a treatment (in this case TPS) and a unit that did not receive the treatment. Synthetic control is particularly useful for a policy analysis of TPS because a) it is well-suited to policy interventions that happen at an aggregated level (Abadie et al. 2015) and b) it gives us a sense of how TPS can affect the over-time outcome path of immigration from particular countries of interest (Abadie and Gardeazabal 2003).²⁹

Very similar to the data employed in the statistical models presented above, we use annual country-level panel data from 1988 to 2015 on remittance inflows and legal immigration to the US. We choose the cases of El Salvador, Honduras, and Nicaragua because they are highly relevant to US immigration policy, given that all of them are geographically proximate in the Western Hemisphere and send significant amounts of immigrants to the US. We restrict our donor pool of control units to Western Hemisphere countries (excluding Canada) whose migrants have never received TPS and that have sufficient coverage on our predictors and outcome variables; this yields a total of 19 members of the donor pool.³⁰

We explore the policy effects of granting TPS on two major outcomes: remittances received per capita and legal immigration to the US.³¹ Our technical approach to synthetic

²⁹ See papers cited here for a more detailed technical discussion of the synthetic control method. For other implementations of synthetic control in political science, see Montalvo 2011; Billmeier and Nannicini 2013; Heersink and Peterson 2016; Heersink et al. 2017.

³⁰ The donor pool countries are: Argentina, Belize, Bolivia, Brazil, Barbados, Chile, Colombia, Costa Rica, Dominican Republic, Ecuador, Guatemala, Guyana, Jamaica, Mexico, Panama, Peru, Paraguay, Trinidad and Tobago, and Venezuela. For remittance synthetic controls, Chile is excluded due to missing data on remittances per capita.

³¹ While elsewhere in this paper we explore the effect of TPS on apprehensions as a proxy for illegal immigration, in the synthetic control context data problems prove to be insurmountable. While in more traditional statistical models we can account for US-side variables that affect apprehensions, such as CBP budget and number of border patrol agents, this proves impossible in a synthetic control model, in which predictors must be characteristics of individual units. Absent a better measure of illegal immigration, we instead focus our policy analysis on remittances and legal immigration to the US.

control is in line with the recommendations of Abadie et al. (2010; 2015).³² Sufficiently available data on remittances per capita does not begin until 1992, and so the pre-treatment outcome period for remittances per capita begins then. Meanwhile, our data on legal immigration (in line with our conventional statistical models) begin in 1988, allowing us to extend the pre-treatment outcome period back further for this outcome. The predictors for the remittances per capita and legal immigration synthetic controls are identical to our statistical models presented above, but in line with the recommendations of Abadie et al. we add as predictors certain years of the respective outcome variable in the pre-treatment period.³³

We expect that for countries whose migrants receive TPS, actual remittances per capita after the granting of TPS should begin to significantly outpace the synthetic control unit; in other words, TPS should increase remittances per capita to a level *higher* than we would expect had TPS never been granted. We also expect that actual legal immigration after the granting of TPS should be significantly lower than for the synthetic control unit; in other words, TPS should decrease legal immigration to a level *lower* than we would expect had TPS never been granted. We have no expectations as to how these policy effects might persist (or not) over the course of TPS implementation, and regard synthetic control as a particularly useful method for exploring potentially heterogenous effects of TPS over time.

El Salvador

We first explore the effect of TPS on El Salvador, whose migrants received TPS in 2001 following an earthquake that caused widespread landslides and property damage. Around 263,000 Salvadorans living in the US in 2001 received TPS, by far the largest population protected by the executive action (CRS 2018). Figure 3 illustrates the results of our synthetic control estimates for El Salvador; in the first panel the outcome is remittances received per capita, and in the second panel the outcome is legal immigration to the US.

Both panels are in line with the general results of the statistical models presented above. While in the pre-treatment outcome period, El Salvador and “synthetic” El Salvador closely

³² To build our synthetic control units, we minimize the mean squared predicted error in the preintervention outcome period for each country-outcome pair. We use Abadie et al.’s (2011) “synth” package in Stata to implement the synthetic control method.

³³ See Appendix E for a more technical discussion of our synthetic control results, as well as for model diagnostics.

match each other in remittances received per capita, in just a few years post-TPS, actual remittances received per capita begin to far outpace “synthetic” El Salvador. This large gap persists through the end of our sample in 2015, suggesting that TPS can have a strong positive and persistent effect on the remitting behavior of migrants in the US. The summary result here is that had TPS not been granted to Salvadorans in the US in 2001, remittances per capita to El Salvador likely would have been much lower than they actually were. This effect does not wear off over time, and the gap generally continues to grow all the way to the end of our sample.

While the match between El Salvador and “synthetic” El Salvador on legal immigration is not quite as close in the pre-treatment outcome period (new arrivals are generally more volatile than remittances per capita), we still see a strong, negative effect of TPS on legal immigration in line with our expectations. Beginning in 2001, the number of new arrivals from El Salvador falls precipitously, while in “synthetic” El Salvador they rise significantly in the post-TPS period. The gap in new arrivals between El Salvador and “synthetic” El Salvador is largest around 2004, about three years after TPS was granted to Salvadoran migrants in the US. After 2004, actual new arrivals from El Salvador begin to increase again, but they never reach the level we would expect given the number of new arrivals we see from “synthetic” El Salvador. Actual new arrivals remain lower than what we would expect all the way through the end of our sample in 2015. This suggests that granting TPS to Salvadoran migrants in the US was effective at decreasing further legal immigration from El Salvador following the 2001 earthquake, and the policy effects of TPS appear to persist long after the executive initially grants it.

Honduras

The synthetic control results for Honduras are largely similar in nature. Honduran migrants received TPS slightly earlier than El Salvador, in 1998, when Category 5 Hurricane Mitch devastated the Honduran economy and killed at least 7,000 people. The estimated number of individuals from Honduras who received TPS is much lower than El Salvador, at about 86,000 (CRS 2018). Figure 4 shows analogous synthetic control results for Honduras; the results again support the proposition that TPS can increase remittances and decrease legal immigration to the US. On remittances per capita, Honduras and “synthetic” Honduras are near-perfect matches prior to the implementation of TPS. But almost immediately after, actual remittances received per capita begin to massively outpace remittances received per capita by “synthetic” Honduras. While there is indeed a dip in remittances to Honduras around 2008 (likely due to the Great

Recession in the US), actual remittances per capita remain far higher than remittances per capita for “synthetic” Honduras. Again, this suggests that granting TPS to Honduran migrants significantly increased the amount of remittances sent back to Honduras over the 15 to 20 years that followed.

TPS also appears to have significantly reduced legal immigration from Honduras, especially in the immediate years following its implementation. In the pre-treatment period, Honduras and “synthetic” Honduras match nearly identically in terms of the number of legal migrants to the US. Right after TPS was granted to Honduran migrants, however, legal migration from Honduras to the US *fell* to below 3,000 while in “synthetic” Honduras it *spiked* to nearly 6,000. Honduras and “synthetic” Honduras eventually re-converge around 2005, suggesting that unlike in El Salvador, TPS may not have had an effect that endured indefinitely. But in the years following 2005, we see divergence again in line with our expectations: legal migration from “synthetic” Honduras begins to far outpace actual legal Honduran immigration. We take these results to suggest that in line with our more general statistical results, TPS was an effective policy lever to increase remittances to Honduras post-crisis and to reduce demand for entry to the US from Honduras.

Nicaragua

In the case of Nicaragua, the effects of TPS are perhaps less clear and attenuated. Along with Honduras, Nicaragua received TPS in 1998 due to Hurricane Mitch. The Nicaraguan population protected by TPS is estimated to be orders smaller than those of El Salvador and Honduras, at about 5,000 individuals (CRS 2018). This suggests that TPS should have less of an effect on both remittances and legal immigration. The results displayed in Figure 5, analogous to those presented for El Salvador and Honduras, largely confirm this expectation. Actual remittances per capita grow slightly larger than those of “synthetic” Nicaragua in the immediate years following TPS, but not nearly as large as the increases we observe for El Salvador and Honduras. In addition, over time this effect completely vanishes, and in the leadup to the Great Recession, “synthetic” Nicaragua actually passes Nicaragua in remittances received per capita. Later on, a re-divergence occurs in line with our expectations, but in general the effect of TPS on remittances received per capita is not nearly as clear in Nicaragua as it is in El Salvador and Honduras. Again, this is likely due to the relatively small number of Nicaraguans who received TPS in 1998.

It appears that TPS did have a negative effect on legal immigration from Nicaragua, in line with our expectations, although this effect does not persist as long as it does in our other cases of interest. Starting in 1998, legal immigration to the US from Nicaragua increases only slightly to around 1,000, while for “synthetic” Nicaragua legal immigration increases dramatically to nearly 2,000. Actual legal immigration from Nicaragua continues to remain below what we would expect given “synthetic” Nicaragua until around 2009. From 2009 onward, it appears that the effect of TPS on Nicaraguan legal immigration becomes non-existent, as actual legal immigration from Nicaragua starts to slightly outpace “synthetic” Nicaragua. However, since the synthetic control algorithm performs relatively poorly in the Nicaraguan case relative to El Salvador and Honduras, we caution against drawing any definitive conclusions for Nicaraguan immigration at the unit level.

Overall, the synthetic control results for El Salvador, Honduras, and Nicaragua suggest that TPS as an executive action can be an effective policy intervention. Temporarily shielding immigrants present in the US after a major crisis in their origin country can a) increase remittances to the origin, potentially mitigating the devastating effects of crisis and b) decrease the demand for legal entry to the US in the process. Especially in the cases of El Salvador and Honduras, two countries for which TPS-affected populations are especially large, instituting TPS seems to have striking effects on remitting behavior and immigration patterns that do not wear off even after many years of TPS renewals.

VII. Conclusions and Implications

For decades, OECD destination countries have experimented with using international economic flows like international trade and foreign aid to control immigration from the developing world, despite the noticeable lack of evidence that such strategies are successful. In this article, we suggest a different route: industrialized countries can decrease immigration with policies that enhance labor market access for those who have already immigrated. In doing so, they can increase remittances to migrant origin countries, a distinct international financial flow that has the power to affect immigration in ways that other flows, notably aid and trade, cannot. We find robust empirical support for this proposition in the case of TPS in the US, demonstrating that granting TPS increases remittances to developing countries whose migrants are eligible, and in the process decreases both documented and undocumented immigration into the US from

those countries. Our synthetic control estimates suggest that TPS can have long-lasting effects on both remitting behavior and legal immigration to the US, and that it can potentially be used as an effective policy lever to control migrant inflows.

These findings have implications for standard neoclassical models of international migration versus the NELM in a developing country context. Our results demonstrate a relationship that traditional models would not predict: while we might expect that increased incomes in developing countries due to remittances would reduce financial constraints and encourage migration, in reality the increase in remittances associated with TPS can serve as an effective deterrent for migration. We do not seek to reject these classic models and their focus on financial constraints and mobility transition. Rather, our results suggest that remittances as a financial flow are different from other income sources. Policies that increase remittances, such as TPS, may not be subject to the same constraints as policies that affect other financial flows like trade and aid. In fact, when viewed through an NELM lens, policies that increase remittances allow households in developing countries to more effectively manage economic risk, decreasing the need for subsequent immigration in the process. In short, our findings indicate that we must understand the conditions under which our classic models of international migration are appropriate, and when alternatives might be more theoretically useful.

Finally, our results speak to recent political battles over programs that grant blanket protections for immigrants, including TPS. Recent executive actions by President Trump and current Secretary of Homeland Security Kirstjen Nelson have ended TPS for more than 400,000 immigrants from El Salvador, Honduras, Haiti, Nicaragua, Sudan, and Nepal. In the context of our argument, these actions constitute revoking labor market access from a sizable immigrant population, likely leading to reduced migrant incomes and higher unemployment. Immigrants who lose labor market access are likely to remit less as a result, effectively reducing household incomes across these developing countries and generating higher demand for entry, both legal and illegal. In other words, revoking labor market protections for immigrants is likely to have unintended consequences: while it might seem that rescinding these protections will reduce the overall immigrant population, it might also generate further immigration via its indirect effects on remittances to migrant origin countries.

Figure 1
Marginal Effect of Remittances on New Arrivals in the US

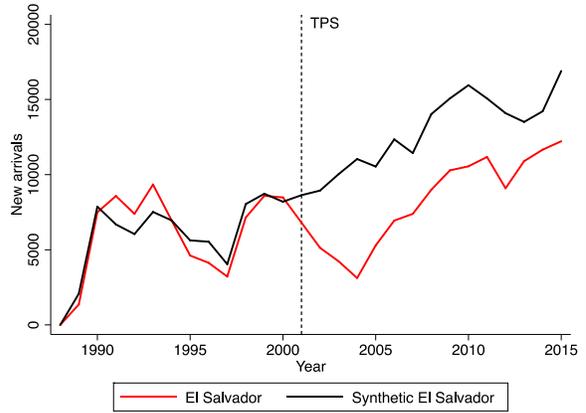

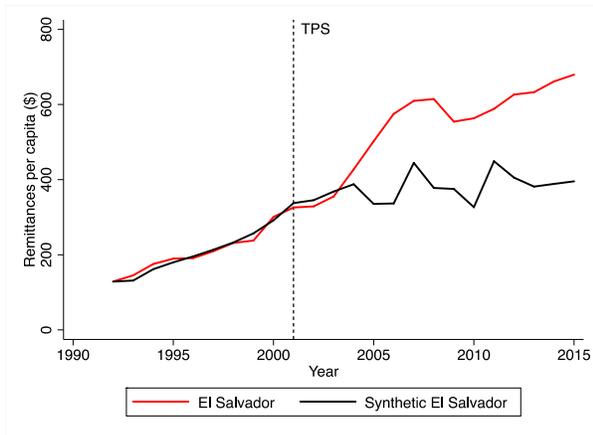

Marginal effects of increase in remittances as a percentage of GDP on New Arrivals. All other variables held at their mean. Model in column (1) of Table 2 used for calculation of marginal effects.

Figure 2
Marginal Effect of Remittances on Apprehensions

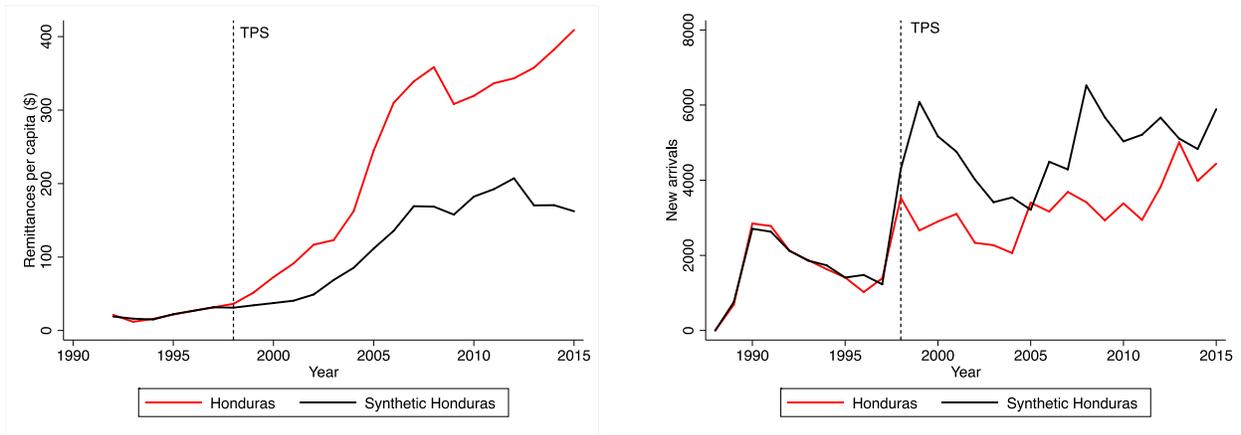

Marginal effects of increase in remittances as a percentage of GDP on apprehensions. All other variables held at their mean. Model in column (1) of Table 3 used for calculation of marginal effects.

Figure 3
Synthetic Control Estimates for El Salvador

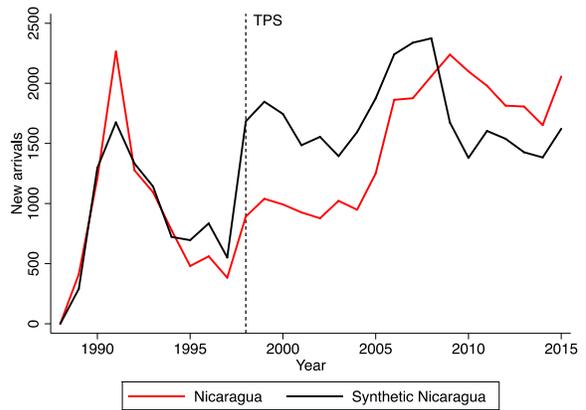

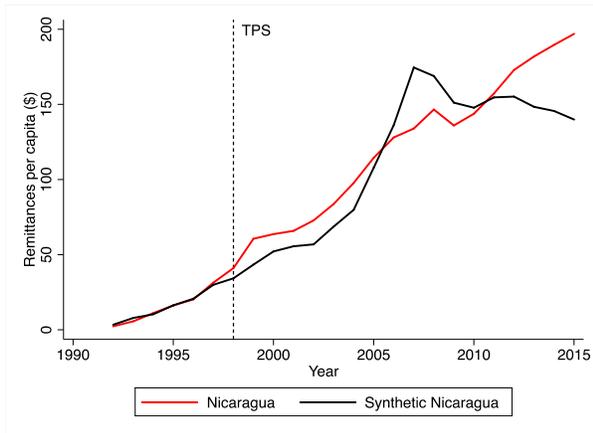

Synthetic control estimates for El Salvador. Panel (1) shows the effect of TPS on remittances per capita while panel (2) shows the effect of TPS on new arrivals to the US.

Figure 4
Synthetic Control Estimates for Honduras

Synthetic control estimates for Honduras. Panel (1) shows the effect of TPS on remittances per capita while panel (2) shows the effect of TPS on new arrivals to the US.

Figure 5
Synthetic Control Estimates for Nicaragua

Synthetic control estimates for Nicaragua. Panel (1) shows the effect of TPS on remittances per capita while panel (2) shows the effect of TPS on new arrivals to the US.

Appendix A: Major Executive Actions on Immigration and Relief Since WWII

Executive action	People affected	President	Year(s)
Eisenhower launches “Operation Wetback”	---	Eisenhower	1954
Foreign-born orphans paroled into custody of military families	923	Eisenhower	1956
Hungarians who escaped after failed uprising against Soviets paroled	31,915	Eisenhower	1956-58
Cuban asylum seekers paroled during Cuban Revolution	621,403	Eisenhower, Kennedy, Johnson, Nixon	1959-72
Chinese who fled to Hong Kong in 1962 paroled	15,100	Kennedy, Johnson	1962
Executive parole of refugees from Vietnam, Cambodia, & Laos	360,000	Ford, Carter	1975-79
EVD enacted for Lebanese (precursor to DED)	14,000 fled Lebanon to US, but exact number unknown	Ford	1976
Deportation of Silva letter-holders suspended	250,000 directly affected; number doubles including dependents	Carter	1977
EVD enacted for Ethiopians	>15,000	Carter, Reagan	1977-82
Soviet refugees paroled	>50,000	Carter	1977-80
EVD enacted for Ugandans	---	Carter	1978
EVD enacted for Nicaraguans	3,600	Carter	1979
EVD enacted for Iranians following Iranian Revolution	---	Carter	1979
EVD enacted for Afghans	---	Carter	1979
Cubans and Haitians involved in Mariel Boatlift paroled	123,000	Carter	1981

EVD enacted for Poles when Polish communist gov't declared martial law	7,000	Reagan	1981-87
Attorney General allowed Nicaraguans to escape deportation if they demonstrated "well-founded fear of persecution" even if denied asylum	~200,000	Reagan	1987
INS compelled to defer deportation proceedings for "compelling or humanitarian factors," undocumented children of noncitizens who applied for LPR after 1986 immigration reform granted temporary legal status	>100,000 families	Reagan	1987
Action for Chinese nationals deferred after Tiananmen square protests	80,000	Bush Sr.	1989
Deportation deferred for spouses and children of individuals who gained LPR through 1986 Immigration Reform and Control Act	Up to 1.5 million	Bush Sr.	1990
DED enacted for Kuwaitis who were airlifted to US during 1990 invasion of Kuwait	2,227	Bush Sr.	1991
DED enacted for certain Salvadorans when their TPS expired, DED later extended until 1994	190,000	Bush Sr., Clinton	1992
Operation Gatekeeper launched to stave off illegal immigration across the border between San Diego and Tijuana	---	Clinton	1994
Cubans paroled in US	~28,000	Clinton	1994
DED enacted for Haitians	40,000	Clinton	1997
Deferred action for noncitizen women and children who suffered assault/battery and petitioned for LPR	---	Clinton	1997
Deportations to El Salvador, Guatemala, Honduras, and Nicaragua temporarily suspended after Hurricane Mitch	150,000	Clinton	1998

DED enacted for Liberians	10,000	Clinton	1999-00 (extended)
Expedited naturalization for green-card holders who enlist in military	---	Bush	2002
Deferred action for foreign students affected by --- Hurricane Katrina, employer verification rules suspended	---	Bush	2005
Cuban Medical Parole Program established (Cuban doctors eligible to apply for parole)	1,574	Bush	2006-
DED enacted for Liberians when TPS expired (TPS later renewed)	3,600	Bush	
Bush pilots and expands Secure Communities Program by asking local law enforcement to share data with ICE	---	Bush	2008
DED for qualified Liberians (new grant)	---	Obama	2009
Deferred action for those whose spouses were US citizens but died (and the children of the deceased, up to the age of 21)	---	Obama	2009
Case-by-case grants of parole-in-place for immediate family of US citizens in military	---	Obama	2010
Haitian orphans paroled if in process of being adopted by US citizens, in response to 2010 Haiti earthquake	---	Obama	2010
Extended Liberian DED status	3,600	Obama	2011-13
Deferred Action for Childhood Arrivals	up to 1.8 million	Obama	2012
Revised previous parole-in-place policy to grant it ordinarily	---	Obama	2013

Expand DACA period from 2 years to 3, expand eligible population, allow parents of citizens and permanent residents to request deferred action and employment authorization for three years, expand provisional waivers to families of US citizens (DAPA), allowed naturalization applicants to pay their application fees via credit card, expand immigrant visa programs	up to 1.8 million	Obama	2014
Obama and Secretary of State John Kerry increase number of refugees admitted into the country annually from 70,000 to 100,000	30,000 annually	Obama	2015 2017
Designated several countries for partial or full travel restrictions, revised H1-B visa procedure, 120-day suspension of Refugee Admissions Act, Border Wall, Sanctuary Cities can't receive federal Grants	---	Trump	2017

Source: Compiled based on summary from American Immigration Council, timeline from Council on Foreign Relations, Congressional Record, and Federal Register.

Appendix B: Countries Included in Statistical Models

Countries included in remittance models:

Afghanistan, Angola, Albania, Argentina, Armenia, Antigua & Barbuda, Azerbaijan, Burundi, Benin, Burkina Faso, Bangladesh, Bulgaria, Bosnia & Herzegovina, Belarus, Belize, Bolivia, Brazil, Barbados, Bhutan, Botswana, Central African Republic, Chile, China, Côte d'Ivoire, Cameroon, Congo – Kinshasa, Congo – Brazzaville, Colombia, Comoros, Cape Verde, Costa Rica, Djibouti, Dominica, Dominican Republic, Algeria, Ecuador, Egypt, Eritrea, Ethiopia, Fiji, Micronesia (Federated States of), Gabon, Georgia, Ghana, Guinea, Gambia, Guinea-Bissau, Equatorial Guinea, Grenada, Guatemala, Guyana, Honduras, Croatia, Haiti, Indonesia, India, Iran, Iraq, Jamaica, Jordan, Kazakhstan, Kenya, Kyrgyzstan, Cambodia, Kiribati, St. Kitts & Nevis, Laos, Lebanon, Liberia, Libya, St. Lucia, Sri Lanka, Lesotho, Lithuania, Morocco, Moldova, Madagascar, Maldives, Mexico, Macedonia, Mali, Myanmar (Burma), Montenegro, Mongolia, Mozambique, Mauritania, Mauritius, Malawi, Malaysia, Namibia, Niger, Nigeria, Nicaragua, Nepal, Oman, Pakistan, Panama, Peru, Philippines, Palau, Papua New Guinea, Paraguay, Romania, Russia, Rwanda, Saudi Arabia, Sudan, Senegal, Solomon Islands, Sierra Leone, El Salvador, Serbia, São Tomé & Príncipe, Suriname, Swaziland, Seychelles, Chad, Togo, Thailand, Tajikistan, Turkmenistan, Tonga, Trinidad & Tobago, Tunisia, Tanzania, Uganda, Ukraine, Uruguay, St. Vincent & Grenadines, Venezuela, Vietnam, Vanuatu, Samoa, Yemen, South Africa, Zambia, Zimbabwe.

Countries included in new arrival and apprehension models:

Argentina, Belize, Bolivia, Brazil, Barbados, Chile, Colombia, Costa Rica, Dominican Republic, Ecuador, Guatemala, Guyana, Honduras, Haiti, Jamaica, Mexico, Nicaragua, Panama, Peru, Paraguay, El Salvador, Trinidad and Tobago, Uruguay, Venezuela.

Appendix C: Variable Descriptions and Data Sources

Variable	Description	Source
<i>Remittance Model</i>		
Civil war	Binary variable that takes value of 1 for years in which the sending country experiences civil war and 0 otherwise	Peace Research Institute Oslo (PRIO)
TPS Dummy	Binary variable that takes value of 1 starting the year a country's migrants receive TPS and continues until TPS is terminated. Coded 0 otherwise.	United States Department of Justice
Exchange rate depreciation	Change in exchange rate between sending country and US	World Bank World Development Indicators
GDP per capita (PPP)	Natural log of GDP per capita in sending country, using PPP	World Bank World Development Indicators
Migrant Population in the US	Natural log of stock of the foreign-born population from sending country in US	U.S. Census 1960 - 2000 and American Community Survey 2000 – 2015
Total number of disasters	Natural log of total number of disasters in sending country	EM-DAT
Population	Natural log of population in sending country	UN World Population Prospects
Remittances as percentage of GDP	Remittances received by sending country as a share of that country's GDP	World Bank Migration and Remittances data
Remittances per capita	Remittances received by sending country divided by population	World Bank Migration and Remittances data
US unemployment rate	Annual unemployment rate	Federal Reserve
US average weekly wage	Average weekly wage	US Bureau of Labor Statistics

New Arrival Model

Number of new arrivals	Number of new arrivals (excluding those who adjusted their status) from sending country	Immigration and Naturalization Service (INS) for pre-2000 and Department of Homeland Security (DHS) post-2000
Ratio of sending country GDP per capita to US	Ratio of GDP per capita in the sending country to the GDP per capita in the US each year	World Bank World Development Indicators
Ratio of sending country Gini coefficient to US	Ratio of Gini coefficient in the sending country to the Gini coefficient in the US each year	United Nations World Income Inequality Database
Ratio of average years of schooling in sending country to US	Ratio of the average years of schooling in sending country to average years of schooling in the US each year	World Bank World Development Indicators
US Foreign aid as % of GDP	Foreign aid received from the US as a percentage of sending country's GDP	OECD Creditor Reporting System (CRS)

Apprehensions

US housing starts	Natural log of number of new residential construction projects begun during year	Mexican Migration Project, updated from 2010-2015 using data from HUD
Number of apprehensions	Number of migrants from each sending country apprehended by Department of Homeland Security	Department of Homeland Security
Number of CBP staff	Natural log of number of Customs and Border Patrol Staff	Department of Homeland Security
Average wait time for asylum	Natural log of average wait time (in days) before decision is made about applications for asylum from each sending country	Transactional Records Access Clearing House (http://trac.syr.edu/immigration/)

Appendix D: Additional Statistical Models

Table D-1: Effect of TPS on Remittances per capita

	(1)	(2)	(3)

US average weekly wage	0.038 (0.045)
US annual unemployment rate	-2.018 (3.641)
Number of observations	698
Chi Square	1732.26

Note: * $p < 0.10$, ** $p < 0.05$. Model(s) estimated using Arellano–Bond linear dynamic panel-data estimation and include robust standard errors. (1) includes non-OECD countries but excludes high-income countries, (2) includes non-OECD countries but excludes high-income and upper-middle income countries, and (3) includes non-OECD countries in Western Hemisphere only.

Appendix E: Technical Discussion of Synthetic Controls and Model Diagnostics

In this appendix, we present a more technical discussion and model diagnostics for the six synthetic controls we run in Section VI. Our implementation of synthetic control for this article closely follows the recommendations of Abadie et al. (2010; 2015), and we implement the method using Abadie et al.'s (2011) “synth” package in Stata. Replication data and code will be posted upon publication.

Countries

Treated units: El Salvador, Honduras, and Nicaragua.

Donor pool: Argentina, Belize, Bolivia, Brazil, Barbados, Chile, Colombia, Costa Rica, Dominican Republic, Ecuador, Guatemala, Guyana, Jamaica, Mexico, Panama, Peru, Paraguay, Trinidad and Tobago, and Venezuela.

As one can observe, our donor pool is restricted to the Western Hemisphere (excluding Canada) to ensure the creation of a relevant comparison synthetic unit. Some countries in the Western Hemisphere, particularly small Caribbean island countries, are excluded due to a lack of data availability on a number of predictors. For the remittance models, Chile is removed from the donor pool due to lack of data availability.

Predictors

The predictors used for the remittances per capita synthetic controls are: natural log of population, natural log of migrant population in US, exchange rate depreciation, natural log of GDP per capita (PPP), natural log of total number of natural disasters, civil war indicator, and certain years of remittances received per capita in the pre-intervention period (exact years depend on when country's migrants received TPS).

The predictors used for the new arrivals synthetic controls are: natural log of migrant population in US, natural log of remittances as a share of GDP per capita, ratio of sending country GDP per capita to US, ratio of sending country Gini coefficient to US, ratio of average years of schooling in sending country to US, civil war indicator, natural log of total number of natural disasters, natural log of population, US foreign aid received as a percentage of GDP, and certain years of new arrivals in the pre-intervention period (exact years depend on when country's migrants received TPS).

All predictors, except for certain years of the dependent variable in the pre-intervention period, are averaged over the entire pre-intervention outcome period.

For the remittances per capita synthetic controls, data availability constrains us to begin the pre-intervention outcome period in 1992. For the new arrivals synthetic controls, the pre-intervention outcome period begins in 1988. This period ends in different years, depending on when a country's migrants received TPS. The end of the pre-intervention outcome period is noted for each country in the sections that follow.

El Salvador models

Remittances per capita model

Pre-intervention outcome period: 1992 – 2000

First year of TPS: 2001

Intervention period: 2001 – 2015
